Abstract

Poly(vinyl alcohol) doped by (Violet methyl) films with different thicknesses were prepared by casting method . The effects of thicknesses on the optical Characterization of poly (vinyl alcohol) films have been studied. The films show indirect allowed interband transitions that influenced by the thicknesses , the optical energy gap has been increased with increasing the thickness and the localized tail widths have been decreased with increasing the thickness.

Keywords: Poly(vinyl alcohol) , Casting method , Optical Properties, Urbach Energy, Influence of thickness variation

تأثير اختلاف السمك على الخصائص البصرية لمركب (بولي فينيل الكحول : المثل البنفسجي)

الخلاصة

تم تحضير اغشية من بوليمر بولي فينيل الكحول المدعمة بالمثل البنفسجي وبأسمك مختلفة بطريقة الصب. تم دراسة تأثير السمك على الخصائص البصرية لأغشية بوليمر بولي فينيل الكحول . لقد وجد في هذا البحث ان الانتقالات الحاصلة نتيجة لتأثير السمك هي انتقالات مسموحة غير مباشرة . وجد ان فجوة الطاقة البصرية تزداد بزيادة السمك، بينما تنخفض طاقة أورباخ بزيادة السمك .

الكلمات المفتاحية: بولي فينيل الكحول، طريقة الصب ، الخصائص البصرية ، طاقة أورباخ ، تأثير اختلاف السمك.

Influence of Thickness Variation on Optical Properties of (Poly Vinyl Alcohol : violet Methyl) Composite

Yaqoob M. Jawad

Introduction

Poly vinyl alcohol (PVA) has been used in many applications since its discovery in 1924 [1]. We have used PVA as a host polymer because PVA is semi – crystalline polymer, good charge storage capacity, having high dielectric strength, flexible light weight materials and can be produced at a low cost [2-3]. Various composite materials had been recently synthesized by starting from different polymers and a wide variety of dopants like metals, inorganic salts, oxides and other particles. The incorporation of the dopants in polar organic polymers can induce pronounced changes in various characteristics of polymers in order to modify and improve its characteristics [4-5].

In the present work is to investigate the optical properties of Poly Vinyl Alcohol (PVA) doped with 4% of Violet methyl with different thicknesses by casting method.

Experimental details

Poly vinyl alcohol polymer (PVA) solution was prepared by incorporation deionized distilled water at solid PVA and then stirred by a magnetic stirrer to 60 °C at one hour, a solution of (Violet methyl) was prepared by incorporation deionized distilled water to (Violet methyl) and then stirred by a magnetic stirrer at room temperature for (½ h). Appropriate mixtures of PVA and (Violet methyl) solution were mixed for (4%) concentration by a different of thicknesses at (5 µm , 10 µm , 20 µm and 40 µm).

The solution was poured on flat glass dish. Homogenous films were obtained after drying in oven for (2 h) at 50 °C. The film thicknesses was measured with a digital micrometer (China Hunan E&K Tools Company) and the average area was (3 x 3) cm². Absorbance and transmittance measurement were carried out using UV/VIS spectrometers in the wave length range (190 – 1100) nm.

Results and discussion

The optical transmission spectra as a function of wavelength at range (190-1100) nm is shown in Figure (1). We can observe from this figure that the transmittance decreases with increasing the thickness. Also may be attributed to creation of levels at the energy band by increasing thickness and this leads to the shift of peak to smaller energies. There are no absorption

spectrum in the visible region because the films are transparent and this result agree with previous studies [6, 7].

Fig. (1): Transmission Spectra of (PVA- violet Methyl) with different thickness films.

Fig. (2). shows the Absorbance as a function of wavelength was found to increase with increasing the thickness.

Fig. (3) Shows the reflectance as a function of wavelength

Fig. (3): Reflectance of (PVA- violet Methyl) with different thickness films.

The following relation could be use for calculating the absorption coefficient (α) [8]:

$$\alpha = \frac{2.303A}{l} \quad \text{----- (1)}$$

Where (A) is the absorption and (l) is the thickness of film.

Fig. (4) show that absorption coefficient increasing with increases of thickness, at short wavelength (α) takes higher value and then increases with decreasing (λ) (increasing photon energy).

Fig. (4): Absorption Coefficient of (PVA- violet Methyl) with different thickness films.

The optical energy gap of the films for allowed indirect transition is determined by the following relation [9]:

$$(\alpha hf)^n = B (hf - E_g) \quad \text{-----(2)}$$

Where (E_g) is the optical energy gap of films, (B) is a constant and (hf) is the incident photon energy. The optical energy gap can be estimated by plotting $(\alpha hf)^{1/2}$ versus photon energy (hf), then extrapolating the straight line part in plot to the photon energy axis. Figures (5) shows the variation of optical energy gap of (PVA: Violet methyl) for different thickness films. The energy gap increases from (1.72, 1.75, 1.78, 1.80) eV as thickness increases from (5, 10, 20, 40) μm . This may be explained by invoking the occurrence of local cross linking within the amorphous phase of polymer, such a way as to increase the degree of ordering in these parts [10], process. Similar behavior had been noticed by Shawki et al. [11].

Fig. (5): Optical Energy Band Gap of (PVA- violet Methyl) with different thickness films.

The absorption is due to the electronic transitions between the valence-band-tail and the conduction-band states and depends exponentially on the photon energy according to the Urbach relation as follows [12]:

$$\alpha = \alpha_0 \exp(h\nu / E_e) \text{-----(3)}$$

Where (E_e) is the Urbach energy, ($h\nu$) is photon energy. Fig. (6) show the relationship between [$\ln(\alpha)$] and the photon energy. The value of (E_e) decreased from about (0.088 eV) for the (5 μm) , (0.072 eV) for the (10 μm) , (0.065 eV) for the (20 μm) and (0.061 eV) for the (40 μm) . Table (1) give the values of optical energy band gap and urbach energy.

Fig. (6) : Relation between $\ln\alpha$ and photon energy for (PVA- violet Methyl) with different thickness films.

Table (1)

Thickness Films (μm)	Optical Energy Gap (eV)	Urbach Energy (eV)
5	1.72	0.088
10	1.75	0.072
20	1.78	0.065
40	1.80	0.062

Conclusions

The PVA doped violet Methyl with different thickness films. Films have been prepared successfully by casting method , The films show indirect allowed inter band transitions that influenced by the thicknesses , the optical energy gap has been increased from about (1.72 eV) for the (5 μm) , (1.75 eV) for the (10 μm) , (1.78 eV) for the (20 μm) and (1.80 eV) for the (40 μm) and the localized tail widths have been decreased from about (0. 088 eV) for the (5 μm) , (0.072 eV) for the (10 μm) , (0.065 eV) for the (20 μm) and (0.061 eV) for the (40 μm) .
