### Abstract

The two-body model of [*Core* + *p(n)*] within the single-particle wave functions of the Woods-Saxon (WS) and Harmonic Oscillator (HO) potentials has been used to study the ground state features such as the neutron, proton and matter densities, the associated root mean square (rms) radii and elastic form factors of exotic  $^{17}\text{F}$  and  $^{19}\text{C}$  nuclei. The long tail manner is clearly shown in the calculated matter densities of these nuclei. According to the calculated results it is found that this model provides a good description on the nuclear structure of above exotic nuclei. The reaction cross sections for these nuclei have been studied using the Glauber model with an optical limit approximation at high energy region.

### Introduction

The study of the structure of exotic (halo) nuclei near the proton and neutron drip lines has become a hot topic in nowadays nuclear physics due to their exotic features [1-3]. The halo phenomena occur mainly due to the small separation energy of the last few nucleons and their occupation on the states with low angular momentum ( $l = 0, 1$ ) [4] which allow the wave function of halo (valence) nucleons to extend to large matter radii [5].

Both on experiments and theories, studying the halo structure is very important to understand the nucleus structure. The halo nuclei must be studied by radioactive beam facilities because they are so short-lived [6].

The few body models can be used to describe halo systems, where the halo nuclei are assumed to be formed by coupling a compact core surrounded by a few weakly bound nucleons [7].

Therefore, we can divide halo systems into two main types: the two-body system where the core nucleus is surrounded by one valence nucleon, such as the one proton halo  $^{12}\text{N}$  and the one neutron halo  $^{15}\text{C}$ ; and the three-body system where the core nucleus is surrounded by two valence (halo) nucleons, such as  $^{11}\text{Li}$  and  $^{14}\text{Be}$ . The three-body system is called Borromean because the two-body subsystems (core plus one nucleon or the di-nucleon) are unbound, while the three-body system is bounded [8].

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

Hamoudi *et al.* [9] have used the TFSM and the BCM to study the ground state densities of exotic  $^9\text{C}$ ,  $^{12}\text{N}$  and  $^{23}\text{Al}$  nuclei. The long tail property is shown in the calculated proton and matter densities of these nuclei. The calculated results of matter densities were in good accordance with the experimental results.

Abdullah [10] has used a three-body model of (Core +  $n$  +  $n$ ) to study the ground state densities of halo  $^6\text{He}$ ,  $^{11}\text{Li}$ ,  $^{12}\text{Be}$  and  $^{14}\text{Be}$  nuclei. The long tail property is shown in the calculated neutron and matter densities of these nuclei. The calculated results of matter densities were in good accordance with the experimental results.

In the present work, the two-body model of [Core +  $p(n)$ ] will be used within the single-particle wave functions of the Woods-Saxon (WS) and Harmonic Oscillator (HO) potentials to study the ground state features such as the neutron, proton and matter densities, the associated root mean square (rms) radii and elastic form factors of exotic  $^{17}\text{F}$  and  $^{19}\text{C}$  nuclei. The reaction cross sections for these nuclei will be studied using the Glauber model with an optical limit approximation at high energy region.

### Theory

For exotic (halo) nuclei the matter density can be written as [11]:

$$\rho_m(\mathbf{r}) = \rho_c(\mathbf{r}) + \rho_v(\mathbf{r}) \quad (1)$$

Where  $\rho_c(r)$  and  $\rho_v(r)$  are the core density and valence (halo) density, respectively.

In this work, the ground state densities of exotic (halo) nuclei have been calculated via two methods, these are WS+WS (Woods-Saxon) and HO+HO (Harmonic Oscillator).

In the WS+WS method, the densities for the core and valence nucleon (proton or neutron) are calculated by solving the eigenvalue problem of Woods-Saxon potential [12]:

$$\frac{\hbar^2}{2m} \frac{d^2 R_{nlj}(r)}{dr^2} + \left[ \epsilon_{nlj} - V(r) - \frac{\hbar^2}{2m} \frac{l(l+1)}{r^2} \right] R_{nlj}(r) = 0 \quad (2)$$

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

Where  $m$  is the reduced mass of the core and single nucleon,  $\varepsilon_{nlj}$  is the single-particle energy,  $R_{nlj}(r)$  is the radial eigen function of WS potential and  $V(r)$  is the potential of the core and can be written as [12]:

$$V(r) = V_0(r) + V_{so}(r) \vec{l} \cdot \vec{s} + V_c(r) \quad (3)$$

Where  $V_0(r)$  is the spin-independent central potential:

$$V_0(r) = \frac{-V_0}{1 + [e^{(r-R_0)/a_0}]} \quad (4)$$

$V_{so}(r)$  is the spin-orbit potential:

$$V_{so}(r) = V_{so} \frac{1}{r} \left[ \frac{d}{dr} \frac{1}{1 + (e^{(r-R_{so})/a_{so}})} \right] \quad (5)$$

and  $V_c(r)$  is the Coulomb potential generated by a homogeneous charged sphere of radius  $R_c$  [13]:

$$V_c(r) = \frac{Ze^2}{r} \quad \text{for } r \geq R_c \quad (6)$$

$$V_c(r) = \frac{Ze^2}{R_c} \left[ \frac{3}{2} - \frac{r^2}{2R_c^2} \right] \quad \text{for } r < R_c \quad (7)$$

The radii  $R_0, R_{so}$  and  $R_c$  are usually expressed as [10]:

$$R_i = r_i A^{1/3} \quad (8)$$

Where  $A$  is the nuclear mass number

In the HO + HO method, the densities for the core and valence nucleon are given by the harmonic oscillator wave functions [11, 14]:

$$\rho_c(r) = \frac{1}{4\pi} \sum_{n\ell} X_c^{n\ell} |R_{n\ell}(r)|^2 \quad (9)$$

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

$$\rho_v(r) = \frac{1}{4\pi} X_v^{n\ell} |R_{n\ell}(r)|^2 \quad (10)$$

Where  $X_{c(v)}^{n\ell}$  represents the number of neutrons or protons, in the sub-shell  $nlj$ .

The matter density of Eq. (1) can be written as [10]:

$$\rho_m(r) = \rho^n(r) + \rho^p(r) \quad (11)$$

Where  $\rho^n(r)$  and  $\rho^p(r)$  are the neutron and proton densities, respectively which can be written as [10]:

$$\rho^n(r) = \rho_c^n(r) + \rho_v^n(r) \quad (12)$$

$$\rho^p(r) = \rho_c^p(r) + \rho_v^p(r) \quad (13)$$

The rms radii of the neutron and proton distributions can be calculated by [10]:

$$r_g = \langle r_g^2 \rangle^{1/2} = \left[ \frac{\int r^2 \rho_g(r) dr}{\int \rho_g(r) dr} \right]^{1/2} \quad g = n, p \quad (14)$$

We study the elastic form factors for considered nuclei using the Plane Wave Born Approximation (PWBA) within the proton density distribution  $\rho_p(r)$ . In the PWBA, the elastic form factors are written as [15]:

$$F(q) = \frac{4\pi}{z} \int_0^\infty \rho_p(r) j_0(qr) r^2 dr \quad (15)$$

Where  $j_0(qr)$  is the zero-order spherical Bessel function and  $q$  is the momentum transfer from the incident electron to the target nucleus. Inclusion the corrections of the finite nucleon size  $F_{fs}(q) = \exp(-0.43q^2/4)$  and the center of mass  $F_{cm}(q) = \exp(b^2q^2/4A)$  in the calculations (when HO wave function is used) needs multiplying the form factors of Eq. 15 by these corrections.

The reaction cross section of considered nuclei is studied by the Glauber model within Optical Limit (OL) approximation which can be expressed as [16]:

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

$$\sigma_R = 2\pi \int [1 - T(b)] b db \left(1 - \frac{B_c}{E_{cm}}\right) \quad (16)$$

Where  $E_{cm}$  is the kinetic energy in the center of mass system,  $B_c$  is Coulomb barrier and  $T(b)$  is the transparency function at impact parameter  $b$ .

In OL approximation the  $T(b)$  is written as

$$T(b) = |S_{el}^{OL}(b)|^2 \quad (17)$$

Where  $S_{el}^{OL}(b)$  is the elastic  $S$ -matrix for the target-projectile system given as [17]:

$$S_{el}^{OL}(b) = \exp[iO_{PT}(b)] \quad (18)$$

$$O_{PT}(b) = \int_{-\infty}^{\infty} dR_3 \int d\vec{r}_1 \int d\vec{r}_2 \rho_P(\mathbf{r}_1) \rho_T(\mathbf{r}_2) f_{NN}(|\vec{R} + \vec{r}_1 - \vec{r}_2|) \quad (19)$$

is the overlap of the ground state densities of projectile and target ( $\rho_P$  and  $\rho_T$ , respectively)

### Results and Discussion

The two-body model of [*Core* +  $p(n)$ ] has been used within the single-particle wave functions of the WS and HO potentials to study the ground state features such as the proton, neutron and matter densities, the associated root mean square (rms) radii and elastic form factors of exotic  $^{17}\text{F}$  and  $^{19}\text{C}$  nuclei. The reaction cross sections for these nuclei have been studied using the Glauber model with an Optical Limit (OL) approximation at high energy region. A structure of a core  $^{16}\text{O}$  [ $^{18}\text{C}$ ] plus valence one proton [neutron] is assumed for  $^{17}\text{F}$  [ $^{19}\text{C}$ ].

The configurations  $\{(1s_{1/2})^4, (1p_{3/2})^8, (1p_{1/2})^4\}$  and  $\{(1s_{1/2})^4, (1p_{3/2})^8, (1p_{1/2})^2, (1d_{5/2})^4\}$  are considered for core  $^{16}\text{O}$  and  $^{18}\text{C}$  nuclei, respectively.

The valence (halo) proton of  $^{17}\text{F}$  is considered as admixture between  $1d_{5/2}$  and  $2s_{1/2}$  with occupation probabilities of 0.4 and 0.6, respectively, the mixing configuration of the valence proton is assumed as following [18]:

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

$$\phi = \left\{ \sqrt{\alpha} \phi_{2s_{1/2}} + \sqrt{1 - \alpha} \phi_{1d_{5/2}} \right\}$$

Where  $\alpha$  refer to the occupation probability of the ( $2s_{1/2}$ ) orbital. While the valence neutron of  $^{19}\text{C}$  is assumed to be in a pure  $2s_{1/2}$ . Table 1 exhibits some features [19 and 20] of halo  $^{17}\text{F}$  and  $^{19}\text{C}$  nuclei.

The WS parameters for stable nuclei ( $^{19}\text{F}$  and  $^{12}\text{C}$ ) and the depth of WS potential ( $V_0$ ) for core nucleons of halo nuclei  $^{17}\text{F}$  and  $^{19}\text{C}$  are taken from Ref. [21] whereas the  $V_0$  for valence nucleon (proton or neutron) and other parameters (*i.e.*  $V_{so}$ ,  $r_0$ ,  $r_{so}$ ,  $a_0$ ,  $a_{so}$  and  $r_c$ ) are adjusted to reproduce the experimental single particle energy of a valence nucleon and matter rms radii.

The HO size parameters  $b_c$  and  $b_v$  are adjusted to reproduce the experimental rms matter radii for core ( $^{16}\text{O}$ ,  $^{18}\text{C}$ ) and halo nuclei ( $^{17}\text{F}$ ,  $^{19}\text{C}$ ), respectively.

The HO size parameter ( $b_c$ ,  $b_v$ ) and WS parameters utilized in our calculations are tabulated in table 2. In tables 3 and 4 a comparison is made between the obtained and experimental results [22-24] of the neutron, proton, core and matter rms radii in fermis for  $^{17}\text{F}$  and  $^{19}\text{C}$  halo nuclei along with the calculated results of Refs. [13 and 22] for  $^{17}\text{F}$  and Refs. [25 and 26] for  $^{19}\text{C}$ . Within errors the obtained results are consistent with experimental ones more than those of above Refs.

Table 5 displays the obtained results of the single-particle energies ( $\varepsilon$ ) for the above investigated nuclei.

**Table 1:** Some properties of nuclei under study

Figure 1 demonstrates the calculated matter densities for  $^{17}\text{F}$  (top panel) and  $^{19}\text{C}$  (bottom panel) calculated via WS+ WS figures (1a and 1c) and HO+ HO figures (1b and 1d) methods.

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

Therein, the blue, red and dashed distributions correspond to core, halo and matter densities, respectively, whereas the shaded areas refer to the experimental matter densities of  $^{17}\text{F}$  [22] and  $^{19}\text{C}$  [27]. The obtained results give a good description of the experimental data and show a characteristic behavior for a halo structure (*i.e.* long tail manner) component in the matter densities.

Figure 2 exhibits the neutron, proton and matter densities displayed as blue, red and dashed curves, respectively. From figures (2a, 2b, 2c and 2d) it is obvious that the proton [neutron] densities have a long tail with respect to the neutron [proton] densities, this means that  $^{17}\text{F}$  [ $^{19}\text{C}$ ] is proton [neutron] halo nucleus.

A comparison of the theoretical matter densities of unstable  $^{17}\text{F}$  and  $^{19}\text{C}$  halo nuclei (dashed curves) with those of their stable isotopes  $^{19}\text{F}$  and  $^{12}\text{C}$  (red curves) are presented in figures (3a and 3d). As shown from these figures, the dashed and red curves are quite diverse. As the valence proton [neutron] in  $^{17}\text{F}$  [ $^{19}\text{C}$ ] is loosely bound, the dashed curves have a longer tail than those of the red curves.

Figure 4 exemplifies the theoretical form factors for  $^{19,17}\text{F}$  figures (4a and 4b) and  $^{12,19}\text{C}$  figures (4c and 4d) calculated using PWBA within proton densities obtained by WS+ WS (left panel) and HO + HO (right panel) methods.

Therein, the red and blue curves correspond to C0 of unstable ( $^{17}\text{F}$ ,  $^{19}\text{C}$ ) and stable ( $^{19}\text{F}$ ,  $^{12}\text{C}$ ) nuclei, respectively. For comparison the experimental data of stable  $^{19}\text{F}$  [28] and  $^{12}\text{C}$  [29] are plotted by blue-dotted symbols. According to these results, each of the red and blue curves has only one diffraction minimum. The minima location of  $^{17}\text{F}$  [ $^{19}\text{C}$ ] has outward and downward [inward and upward] shift as compared with the minima of  $^{19}\text{F}$  [ $^{12}\text{C}$ ].

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

**Figure 3:** Distributions of the matter density for unstable ( $^{17}\text{F}$ ,  $^{19}\text{C}$ ) nuclei and their stable isotopes ( $^{19}\text{F}$ ,  $^{12}\text{C}$ )

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

**Figure 4:** Elastic form factors of unstable ( $^{17}\text{F}$ ,  $^{19}\text{C}$ ) nuclei and their stable isotopes ( $^{19}\text{F}$ ,  $^{12}\text{C}$ )

The reaction cross sections ( $\sigma_R$ ) of  $^{17}\text{F}$  and  $^{19}\text{C}$  on  $^{12}\text{C}$  target have been calculated using the Glauber model with an optical limit approximation at high energy region and tabulated in table 6 along with experimental data [24]. From this table one can see that the calculated results of  $\sigma_R$  are in a good agreement with experimental data.

## Density Distributions of Exotic $^{17}\text{F}$ and $^{19}\text{C}$ Nuclei Studied by the Two-Body Model

Alzahraa Yaseen A. Alsajjad and Ahmed N. Abdullah

**Table 6:** Calculated reaction cross sections of  $^{17}\text{F}$  and  $^{19}\text{C}$  along with experimental data.

Halo nuclei	Calculated $\sigma_R$ (mb)	Experimental $\sigma_R$ (mb) [24]	Energy (MeV) [24]
$^{17}\text{F}$	789	$982 \pm 32$	650
	970	$966 \pm 56$	700
$^{19}\text{C}$	1240	$1231 \pm 28$	960

### Conclusions

According to the calculated results it is found that the two-body model of  $[Core + p(n)]$  within the single-particle wave functions of the WS and HO potentials provides a good description on the nuclear structure of exotic  $^{17}\text{F}$  and  $^{19}\text{C}$  nuclei. The long tail manner is clearly shown in the matter densities of these nuclei. The structure of the halo (valence) proton in  $^{17}\text{F}$  is a mixed configuration of  $1d_{5/2}$  and  $2s_{1/2}$  with dominant  $2s_{1/2}$  whereas the structure of the halo (valence) neutron in  $^{19}\text{C}$  is in a pure  $2s_{1/2}$ . The calculated results of  $\sigma_R$  using the Glauber model with an optical limit approximation at high energy region are in a good agreement with experimental data.
