To my family, who support me with their kindness, patience and encouragement.

Allah bless you all

Maysam

Acknowledgements

Praise be to Almighty Allah, the most Merciful and Compassionate, For the ever gifts He has granted me without which this work would not have seen the light. Thanks are to His prophet Muhammad (May the Blessings and peace of Allah be upon him), the ever moral guidance for the humanity.

I would like to express my gratitude to my supervisors, Prof. Dr. Sabah Atwer Salman and Prof. Asad. I would like to thank them for their illuminating remarks and continuous support which encouraged me a great deal to complete this work.

Thanks are due to the Dean of all the Staff of the Department of Physics for their assistance and especially for Marwa Rashed Jwameer.

Finally, thanks are due to all who have helped me throughout this work, be they relatives or friends.

Abstract

The pure films of polymer (polyvinyl alcohol (PVA)) filled with iron salts (FeCl_3 and $\text{Fe}(\text{NO}_3)_3$) with different concentrations ((1, 3, 5, 7 and 9) wt%) have been prepared by using casting technique. The

The effect of iron salts concentration on the thermal properties of (PVA- iron salts) composites films have been investigated.

The experimental results of (PVA-iron salts) composites films show that the thermal conductivity decreases with increasing the filler content while the glass- transition temperature increases with increasing the filler content.

Also the effect of iron salts concentration on the optical parameters such as transmittance, absorbance, absorption coefficient, refractive index, extinction coefficient and real and imaginary parts of dielectric constant of (PVA-iron salts) composites films were studied.

The experimental results of (PVA-iron salts) composites films show that the transmittance decreases with increasing the filler content while the absorbance increases with increasing the filler content. The

Also the effect of iron salts concentration on the bonds of pure (PVA) film were studied.

The experimental results show that the absorption bands of the bonds O-H, C-H, C=O, C=C, C-O, C-C and CH₂ of pure (PVA) film shift to higher wavenumbers with increasing the filler content in the doped (PVA) film with iron salts.

أظهرت النتائج العملية لأغشية مترابكات (املاح الحديد-PVA) بان التوصيلية الحرارية تقل مع زيادة نسبة التشويب لأملاح الحديد بينما درجة حرارة الانتقال الزجاجي تزداد بزيادة نسبة التشويب لأملاح الحديد.

كذلك تم دراسة تأثير تركيز أملاح الحديد على المعلمات البصرية (النفاذية، الامتصاصية، معامل الامتصاص، معامل الانكسار، معامل الخمود وثابت العزل بجزئيه الحقيقي والخيالي) لأغشية مترابكات (املاح الحديد-PVA).

أظهرت النتائج العملية لأغشية متراكبات (املاح الحديد-PVA) بأن النفاذية تقل مع زيادة نسبة التشويب لأملاح الحديد بينما الامتصاصية تزداد مع زيادة نسبة التشويب لأملاح الحديد. معامل الامتصاص، معامل الانكسار، معامل الخمود وثابت العزل بجزيئيه الحقيقي والخيالي يزدادون بزيادة نسبة التشويب لأملاح الحديد، وكذلك اظهرت النتائج بأن الانتقالات الالكترونية هي إنتقالات إلكترونية مسموحة غير مباشرة، ان فجوة الطاقة (E_g) وطاقة اوريباخ (E_u) تقل بزيادة نسبة التشويب لأملاح الحديد.

كذلك تم دراسة تأثير تركيز املاح الحديد على الاواصر لغشاء (PVA) النقي.

أظهرت النتائج العملية بان حزم امتصاص الاواصر O-H, C-H, C=O, C=C, C-O,

C-C and CH₂ لغشاء (PVA) النقي تنحرف نحو الاعداد الموجية الاعلى بزيادة نسبة

1-1 Introduction

Polymers, as plastics and rubbers, pervade our lives and we come across them in many different forms. As such, their physical properties have great importance, and an understanding of them is vital for their uses in technology and engineering [1].

Polymers possess material properties which are distinctly different from those exhibited by metals, ceramics and glasses. Metals on heating can be transformed from hard solids to low viscosity liquids over a relatively small temperature range. Ceramics exhibit a hardness that does not vary significantly with temperature up to the melting point and

have poor impact properties and low elasticity. In contrast, polymers

[1].

Polymers are extremely long chained molecules that have repeating units [2,3]. In many polymers, very few interactions exist between the chains except Vander Waals forces. If Vander Waals forces were the only forces holding the chains together, little cohesion would exist between chains. The resulting material would likely be a liquid or a gel, which is not the case. Polymers are generally solids and this is due to entanglements of the long molecules. To have stable entanglements that

restrict the flow of the polymer chains, polymers must have a critical molecular weight that is dependent on the flexibility of the backbone and the steric hindrance within the molecule [2].

The importance of the entanglements on the cohesion can be seen in cases when an assortment of different length strings are mixed into a ball, the short pieces of string could be easily removed. The intermediate length pieces of string could be removed only with some effort but it would take a substantial amount of effort to remove the longest strings. These entanglements influence the viscoelastic, melt viscosity and mechanical properties of the polymer [2].

Some characteristics of amorphous polymers are that they have good mechanical properties and good dimensional stability.

Amorphous polymer also shrink consistently during cooling, as well as being inherently transparent [4].

Figure (1-1): Representation of polymer chains in an amorphous polymer [2,4]

Semi-crystalline polymers generally orient themselves in a lamella structure [2]. An example of lamellar structure is the gills of a fish or mushroom. For a polymer to crystallize, the conditions during the cooling of a polymer melt have to allow the polymer chains to arrange themselves. The crystal sheets may be as thin as (100 to 200) Å; between these crystalline sheets, there are amorphous regions [2]. It was found that as the lamellar structure thickness increased, the thermal conductivity of polyethylene did as well [5]. Figure (1-2) is an illustration of how polymer chains orient in a lamellae structure. This figure illustrates three possible ways the chains could orient in two dimensions, which can be expanded in to three dimensions. Semi-

crystalline polymers have anisotropic shrinkage, very good electrical properties and are chemically resistant to some harsh environments [4].

1-2 Polymer Structure

In the teaching of physical polymer science, a natural progression of material begins with chain structure, proceeds through morphology and leads onto physical and mechanical behavior. Polymer chains have three basic properties:

- 1- The molecular weight and molecular weight distribution of the molecules.
- 2- The conformation of the chains in space. The term conformation refers to the different arrangements of atoms and substituents of the polymer chain brought about by rotations about single bonds. Examples of different polymer conformations include the fully extended planar zigzag, helical, folded chain and random coils.

1-3 Classification of Polymers

1-3-1 Thermal Classification of Polymers

Polymers are classified according to the effect of temperature to:

1-Thermoplastic Polymers

The properties of these polymers are changed by the effect of temperature. When the temperature increases, they become flexible and

sticky, by lowering the temperature, these polymers return to their original solid state. This is because the molecules in a thermoplastic polymer are connected by relatively weak intermolecular forces (Vander Waals forces). When heated, these molecules can slide over each other as in polystyrene, polyethylene, polyvinyl alcohol and polyvinyl chloride [7].

2- Thermoset Polymers

These polymers are chemically changed when heated. Thermosets are usually three-dimensional networked polymers in which there is a high degree of cross-linking between polymer chains. After being heated, these polymers become insoluble, hard, non-conductive of heat

1-3-2 Chemical Classification of Polymers

Polymers are classified depending on the structural composition to:

1- Liner Polymers

The essential structural units for these polymers are one molecular series of certain length connected with each other in a linear shape, it does not contain the branch except the totals twisted which are part of monomer, as in figure (1-3-a).

It is the same type of polymer which is used in the present study.

2- Branched Polymers

Here the long chain is branching and it is characterized by this type of installation that the branches are as a ladder or a Comb or as a Crusader. The branches have different lengths, as in figure (1-3-b).

3- Cross Linked Polymers

In this type, the chemical bonds are interwoven with each other in a complex way. The format string consists of three dimensional polymer chains linked together by more than one site, or when we use monomers containing effective totals rather than being included in two effective totals, as in the figure (1-3-c) [10].

Figure (1-3): The different types of polymeric chains [11]

1-3-3 Polymers Dependence on Homogeneity

Polymers are classified depending on the homogeneity of repeating units in to:

1- Homopolymers

When the building blocks of a polymer are of one type, as in polytherphethals ethylene.

2- Copolymers

When the building blocks of a polymer are more than one type, as in the polymer (styrene – butadiene).

3- Composite Polymers

Molecular Weights

Polymers are classified depending on the chain's lengths and molecular weights in to:

1- Mono Disperse Polymers

All Particles in this case are of equal size and have the same weight, this type of polymers is not common.

2- Poly Disperse Polymers

Polymers resulting from polymerization consist of a wide range of molecular weights, i.e, different chains in length, where all chains do not

grow during the polymerization process to the length itself, this means that the existence of a diverse distribution of the chains and thus there is a multiplicity of molecular weights [13].

1-4 Polymer Sources

Polymers are of two main sources:

1- Natural Polymers

They are compounds which come from plant or animal such as timber, cotton, natural rubber, wool and silk. The natural food which is the natural polymer is starch, protein or cellulose [9].

2- Synthetic Polymers

1-5 Characteristics of Polymers

- 1- Low density.
- 2- Low coefficient of friction.
- 3- Good corrosion resistance.
- 4- Good mould ability.
- 5- Excellent surface finish can be obtained.
- 6- Can be produced with close dimensional tolerances.
- 7- Economical.
- 8- Poor tensile strength.
- 9- Low mechanical properties.
- 10- Poor temperature resistance.
- 11- Can be produced transparent or in different color [15].

1-6 Polymer Composites

A composite is a material system composed of a combination of two or more materials that differ in form or material composition. The properties of a composite are different from those of its materials [16,9]; it is also cohesive in structure. The composite is comprised of two major components: the matrix which is the basic material and the additives. The matrix is the basic material, serving to enclose the composite and give it a bulk form. It surrounds other constituents and makes them more cohesive to form a "compact system". Additives are constituents added to polymers to provide them with specific properties and improve basic properties. These constituents are added in a granular form or as small particles. Additives can increase the overall conductivity, reduce porosity, improve friction and some magnetic properties ...etc [13,17].

Composite materials are often classified by matrix type or reinforcement type. In addition, there are ceramic matrix composites (CMC), ceramic matrix composites (CMC) and polymer matrix composites (PMC). The high cost of production, difficulty of manufacture and higher density of MMC. CMC has limited most of these materials to special applications. Lower materials costs and relative ease of processing have allowed PMC composites to be integrated into many applications in everyday life. Composites are also classified according to the reinforcement type. Particulate composites are ones that use small particles, platelets, flakes or rods to reinforce the matrix, where the dimensions of the reinforcement are roughly similar [13].

1-7 Molar Mass and Degree of Polymerization

Many properties of polymers show a strong dependence upon the size of polymer chains, so that it is essential to characterize their dimensions. This normally is done by measuring the molar mass (M) of a polymer which is simply the mass of (1 mole) of the polymer and usually is quoted in units of (g mol^{-1}) or (Kg mol^{-1}). The term 'molecular weight' is still often used instead of molar mass, but is not preferred because it can be somewhat misleading. It is really a dimensionless quantity, the relative molecular mass, rather than the weight of an individual molecule which is of course a very small quantity (e.g. $\sim 10^{-19}$ – $\sim 10^{-18}$ g for most polymers). By multiplying the

of a homopolymer is related to the degree of polymerization (x), which is the number of repeat units in the polymer chain, by the simple relation:

$$M = xM_0 \dots\dots\dots(1-1)$$

Where M_0 is the molar mass of the repeat units. For copolymers the sum of the products (xM_0) for each type of repeat unit is required to define the molar mass [18].

1-8 Factors Affecting Polymer Properties

Chemical and physical properties of polymers are determined by three major factors:

1-8-1 Chemical Bonds and Binding Forces

Chemical bonds and binding forces govern the physical properties of polymer. They can be divided into two groups. The basic chemical bonds include covalent, ionic, hydrogen and metallic which are responsible for binding atoms to form the polymer molecule. Most polymers, especially the organic ones have covalent bonds. The other group is the secondary forces that bind polymer molecules of the same chain or between different chains, resulting in

Remove Watermark Now

The arrangement and binding of the repeating units of the polymer, the type of the substitution groups and chemical bonds offer the polymers a special structure and distinguished chemical and physical properties [21].

1-8-3 Average Molecular Weight

Polymers are distinguished from other materials that they have relatively large molecular weight. Most physical properties of polymers depend on their molecular weights. Polymer properties such as strength, conductivity and solubility change with their molecular weight [22].

1-9 Preparation Methods of Polymer Films

1-9-1 Casting Method

To prepare film in the casting method, a certain amount of polymer material is dissolved in a suitable organic solvent such as Tetrahydrofuran (THF). To obtain a homogenous solution, the speed of solvent evaporation must be reduced and the preparation time must be long as mentioned in chapter (3) [23].

1-9-2- Spin Casting Method

In this method, little amount of polymer solution is precipitated on the center of the rotating disc. The rotation is achieved by spinning in very high speed where the acceleration of disc centrifuging of used polymer solution over the rotating disc forms a thin film. The thickness of a prepared film in this method depends on the concentration of the polymer solution must be diluted and rotation speed must be increased [20].

1-9-3 Dip Coating Method

In this method rotating disc is dipped in already prepared polymer solution. Then, the rotating is removed and put on a balanced horizontal surface to obtain a homogenous thickness for the film. The thickness of the film can be controlled by the concentration of the polymer solution and the time of dipping. The dip coating method is effective in the preparation of metal-oxide-film where the polymer material is oxidized immediately after being removed from the solution [20].

1-9-4 Sol-gel Method

This method is similar to dip coating method, but the rotating disc in this method is moving upward and downward in a constant speed. The movement of the rotating disc depends on the type of the prepared solution. For example (PVA+ Barium nitrate) [20].

1-9-5 Languimer-Blodgett (LB) Method

This is one of the important methods of preparing homogenous thin films of very small thickness of one nanometer (1nm), known as molecular structures. Molecular structures thickness can be controlled by increasing film layers. The latter can be used in the Field Effect Transistors (FET),

electrochemical polymerization in non-organic matter that takes place in a simple cell containing two electrodes-an anode and cathode-as well as electrolyte solution. The cell is provided with the required voltage to carry out the oxidation and reduction processes. This process is performed by power supply connected to the electrodes of the cell which are coated with the polymer material after a certain period of time. The type of the polymer material depends on the type of the electrolyte solution inside the cell. The electrolyte solution consists of monomer, salt, and solvent [24]. Figure (1-4) shows the main parts of an electrochemical cell:

- 1- cell
- 2- Electrodes
- 3- Electrolyte solution

partial hydrolysis process of polyvinyl acetate [26]. Table (1-1) shows the physical properties of polyvinyl alcohol (PVA).

Because of (PVA) is a polymer obtained by the hydrolysis process, the (PVA) has particularly notable properties than other thermoplastic. Polyvinyl alcohol (PVA) is a water-soluble synthetic polymer. Due to the characteristics of easy preparation, we have good biodegradability, excellent chemical resistance and good mechanical properties: (PVA) has been used on many biomaterial applications [27]. Doping of polymers attracted the scientific and technological researchers, because of their wide applications. The dopant in polymer can change the molecular structure and hence the microstructure as well as macroscopic properties of the polymer [28].

Table (1-1):
The physical properties of polyvinyl alcohol (PVA)
[29]

Appearance	White –to-cream granule powder
Solution PH	(5.0-7.0)
Bulk Density, kg/m³	(400-432)
Specific Gravity	1.30
Resin Density, kg/m³	1294
Specific Volume , kg/ m³	7.7×10^{-4}
Specific Heat, J/kg.K	1674
Thermal Conductivity, W/(m.K)	0.2
Melting Point (unplasticized) °C	(230) for fully hydrolyzed grades ,(180-190) for partially hydrolyzed grades
T_g °C (dry film)	(75-85)
Storage Stability (solid)	Indefinite when protected from moisture
Flammability	Burns similarly to paper
Stability to Sunlight	Excellent

Remove Watermark Now

mechanism was assumed to interpret the electrical conduction. The (ESR) studies of (PVA) filled with various mass fractions of FeCl_3 revealed very complicated spectra due to hyperfine and fine structure [32].

Lee et al. (2008) studied the properties of nano-(ZnO/PVA/polyethylene oxide (PEO)) composite thin films, to explore the possibility of the mechanical and electronic properties of ZnO in the form of nanoparticles. Ultraviolet absorption and thermal behavior of thin films were determined as a function of nano-ZnO content up to (15 wt%).

The (UV-V) region is a transmission of films, nano-ZnO particles not only absorbs (UV) light, but also scatters visible light. Nano-ZnO (PVA) and (PEO) suspensions of (1%) ZnO have better transmission of visible light compared to higher ZnO concentrations [33].

El-Khodary (2009) studied the vibrational, thermal, optical and magnetic investigations of (PVA) films filled with FeCl_3 and CoCl_2 . An assignment of the most notably infrared (IR) peaks was done. Significant vibrational deformations of certain (IR) peaks with filling were studied. The main characterizing temperatures were recorded, assigned and their (FL) dependence were studied using differential scanning calorimetric (DSC). The

thermal analysis depicts better thermal properties of the filled polymer with

behavior characterized by localized magnetic moments. A correlation between vibrational, thermal, optical and magnetic properties was done [34].

Hema et al. (2009) studied the structural and thermal studies of (PVA: NH_4I). A new proton-conducting (PVA: NH_4I) polymer electrolyte has been prepared and characterized using (XRD), (FTIR) and (DSC). From the (FTIR) result, they have confirmed the interaction between the added salt and the host polymer matrix because of which there is variation in thermal constants (T_g and T_m), structural (crystallinity) and also the conductivity properties (σ_{dc} , E_a), etc. of the prepared polymer electrolytes [35].

El-Khodary (2010) studied the evolution of the optical, magnetic and morphological properties of (PVA) films filled with CuSO_4 . The experimental results showed that the optical energy gap and the Urbach energy decreased with concentration of the salts increase in the polymer composite [36].

Nasar et al. (2010) studied the structural, mechanical and thermal properties of polymer composites of polyvinyl alcohol with inorganic material. They found that the thermal conductivity of the (polyvinyl alcohol/sodium sulphate) and (polyvinyl alcohol/lithium sulphate) composite decreased with concentration of the salts increase in the polymer composite [37].

parameters like absorbance, reflectance, refractive index and extinction coefficient [38].

Abdelaziz (2011) studied the cerium (III) doping effects on optical and thermal properties of (PVA) films. The results showed that the thermal stability and the glass transition temperature of the doped films increased with the increase in concentration of the cerium. Both (XRD) and (FTIR) confirm the complex formation due to the presence of new peaks, broadening and shifting of the absorption bands [39].

Abdullah (2012) studied the optical absorption of polyvinyl alcohol films doped with nickel chloride. The absorption spectral analysis showed that the optical energy gap was due to the direct and indirect allowed optical transitions. The optical energy gap of the films decreased with increasing the localized states in the optical band gap and also with increase of NiCl_2 content [40].

Ahmad et al. (2012) studied the electrical and optical properties of (PVA/LiI) polymer electrolyte films. They found that the optical energy gap from direct allowed transition decreases from (5.56 eV) of pure (PVA) to (4.95 eV) of (PVA+20%LiI) [41].

Abdullah et al. (2015) studied the complex formation of (PVA/PEO/CuCl₂) solid polymer electrolyte. The experimental results of (PVA/PEO/CuCl₂) films showed that the incorporation of CuCl₂ into the polymeric system caused charge transfer complexes in the blend polymer. The (PVA/PEO/CuCl₂) solid polymer electrolyte films exhibited good (UV) shielding properties in the wavelength range from (190 - 400) nm [46].

Deshmukh et al. (2016) studied the Influence of K₂CrO₄ doping on the structural, optical and dielectric properties of polyvinyl alcohol/K₂CrO₄ composite films. Ultraviolet–visible spectroscopy, X-ray diffraction, thermogravimetric analysis, optical microscopy, scanning

electron microscopy and dielectric devices are used in this research. Microscopic studies reveal that K_2CrO_4 was homogeneously mixed with polyvinyl alcohol matrix due to interfacial interaction between polyvinyl alcohol and K_2CrO_4 . The composite films showed very high dielectric constant and relatively low dielectric loss. Hence, such composite materials with improved dielectric properties could be useful for the fabrication of electrical charge storage device [47].

1-15 Aims of The Works

1- Preparing the thin films of polymer polyvinyl alcohol (PVA) and filled them with iron salts ($FeCl_3$ and $Fe(NO_3)_3 \cdot 9H_2O$) with different
